

### ABSTRACT OF THE DISCLOSURE

A combination therapy for treating a mammalian subject suffering from an autoimmune or alloimmune disease comprises administering to the subject a drug treatment which results in at least partial remission of one or more symptoms of the autoimmune or alloimmune disease, and administering to the subject autologous mammalian blood which has been modified extracorporeally by exposure to at least one stressor selected from an oxidative environment, an electromagnetic emission and a temperature above or below body temperature. The modified mammalian blood is administered to the subject in an amount which is sufficient to maintain the remission of the symptoms of the autoimmune or alloimmune disease.
